CLIMATOLOGY OF ATLANTIC TROPICAL CYCLONES BY TWO AND ONE-HALF DEGREE LATITUDE-LONGITUDE BOXES

John R. Hope, National Hurricane Center, Miami
Charles J. Neumann, Spaceflight Meteorology Group, Miami

This paper presents a climatology and brief statistical analysis of Atlantic tropical storms and hurricanes by 2½-degree latitude-longitude boxes. It extends and refines the climatological charts of Colon (1953) to include data for the years 1950-1968. The period of record used in this study extends from 1886 through 1968, a total of 83 years, and includes 667 storms and hurricanes passing through a total of 12,340 2½-degree latitude-longitude boxes.

In the previous study by the authors (1968) it was found necessary to compute storm frequencies by 2½-degree boxes instead of 5-degree boxes because there were large differences in the number of storms which passed through the four 2½-degree boxes comprising the larger boxes. It was decided, therefore, to compute certain climatological data by 2½-degree boxes for the entire hurricane season, for the early season 1 May through 15 July, for the middle season 16 July through 20 September, and for the late season 21 September through 30 November. In addition, computations were made for 16 overlapping 30-day periods beginning every 10 days between 1 June and 30 November.

The basic data source was the North Atlantic Tropical Cyclone deck, number 988, compiled by the National Weather Records Center at Asheville, N. C.. This deck was previously used by the authors (1968) at which time corrections were applied where needed and the deck brought up to date through the 1968 season. The original hurricane deck is based on tracks given by Cry, Haggard, and White (1959), and Cry (1965).

The following information was computed for all periods:

1. The number of tropical storms or hurricanes passing through each 2½-degree latitude-longitude box. Tropical depression stages are not included.

2. Resultant direction and mean scalar speed of storms or hurricanes as they entered each 2½-degree latitude-longitude box. These computations were not made for any box if the storm count was less than five.

For early, middle, and late season storms the 95 percentile scalar speed of storms as they entered each box was computed, assuming a normal distribution of the scalar speeds. Finally the Poisson probability of occurrence of no storms; at least 1 storm; and at least 2 storms in each of the boxes was computed for early, middle, and late storms, and for the entire season. The computations were performed and the charts printed by the University of Miami IBM 7040 computer.

Except for the following remarks the charts described above are presented in this paper without analysis or interpretation.

On the charts depicting direction and speed of storm movement, the ratios of resultant to scalar speed measure the steadiness or constancy of direction of storm movement.

It was found that a simple Poisson probability function, using the sample mean as the maximum likelihood estimate of the population mean, yields probability values that are in good agreement with the observed relative frequencies of the events considered. Considering the entire hurricane season, a comparison of observed relative frequencies and computed Poisson probabilities for three boxes which are near or include Cape Hatteras, Miami, and New Orleans respectively, is shown in Table I.

TABLE I

Comparison of Observed Relative Frequencies and Poisson Probabilities of Specified Occurrences of Tropical Storms or Hurricanes, 1 May through 30 November, 1886-1968

Box	Observed Relative Frequency of Occurrence			Poisson Probability of Occurrence		
	0	at least 1	at least 2	0	at least 1	at least 2
35.0-37.5N 72.5-75.0W	.43	.57	.21	.41	.59	.23
25.0-27.5N 80.0-82.5W	.46	.54	.19	.43	.57	.22
28.5-30.0N 85.0-87.5W	.53	.47	.16	.54	.46	.13

The preliminary results shown in this paper provide material which is being used for further study in hurricane climatology and forecasting at the National Hurricane Center in Miami.

--

We gratefully acknowledge the assistance of S/Sgt. Wayne King of the Office of the Chief, Aerial Reconnaissance Coordination, Atlantic Hurricanes, Miami, Florida.
